

REAL-DATA GROUNDING

Lighting up Suez & Panama from real PortWatch

Precedence resolver for a canal node: real PortWatch transit > real canal scrape > hardcoded baseline.

PRECEDENCE-LADDER DECISION FLOW

TRANSIT_DROP_RATIO → RISK LEVEL

applied on the PortWatch drive path

≥ 0.50	CRITICAL	transits collapse
≥ 0.30	HIGH	severe rerouting
≥ 0.15	MODERATE	draft / queue strain
else	LOW	normal flow

None / short history → LOW

WHY IT MATTERS

2

**highest-leverage
SSI nodes lit up**

- ▶ Canal scrape almost always returns is_synthetic=True — nodes were dark.
- ▶ Resolver overlays real IMF PortWatch transit counts by precedence.
- ▶ Suez ~12% of global trade · ~30% of container traffic; Panama ~5-6%.

Market context: illustrative · public sources

PRECEDENCE RESOLVER — APPLY_LIVE_CANAL_NODES (R267)

- ▶ Precedence: real PortWatch transit > real canal scrape > baseline.
- ▶ Escalate-only & ratchet-free: a cleared reading never downgrades a node below its pristine baseline.
- ▶ A present real signal is never overridden by the synthetic feed.
- ▶ Effect: the two highest-leverage SSI chokepoints — once dark behind a near-always-synthetic scrape — now run on real data.
